## agent

(agent state & options)

Creates and returns an agent with an initial value of state and zero or more options.

Options:

:error-handler handler-fn

:error-mode mode-keyword

The handler-fn is called if an action throws an exception. It's a function taking two args the agent and the exception. The mode-keyword may be either :continue (the default) or :fail

```
(do
  (def x (agent 100))
  (send x + 5)
  (sleep 100)
  (deref x))
=> 105
```

[top](#)

  (send x (fn [n] (/ n 0)))

(and true true)  
=> true
```

```
(and true false)  
=> false
```

[top](#)

## any-pred

```
(any-pred p1 & p)
```

Takes a set of predicates and returns a function `f` that returns the first logical true value returned by one of its composing predicates against any of its arguments, else it returns logical false. Note that `f` is short-circuiting in that it will stop execution on the first argument that triggers a logical true result against the original predicates.

```
((any-pred number?) 1)  
=> true
```

```
((any-pred number?) 1 "a")  
=> true
```

```
((any-pred number? string?) 2 "a")

```
(any? #(>= % 10) [1 5 10])
=> true
```

[top](#)

## app/build

```
(app/build name main-file file-map dest-dir)
```

Creates a Venice application archive that can be distributed and executed as a single file.

E.g.:

```
(app/build "test"
  "chart.venice"
  { "chart.venice" "./foo/chart.venice"
    "utils.venice" "./foo/utils.venice" }
  ".")
```

Loading Venice files works relative to the application. You can only load files that are in the app archive.

If for instances "chart.venice" in the above example requires "utils.venice" just add (load-file "utils") to "chart.venice".

The app can be run from the command line as:

```
> java -jar venice-1.7.17.jar -app test.zip
```

Or with additional Java libraries (all JARs in 'libs' dir):

```
> java -cp "libs/*" com.github.jlangch.venice.Launcher -app test.zip
```

[top](#)

## app/manifest

```
(app/manifest app)

```
(apply + [1 2 3])  
=> 6
```

```
(apply + 1 2 [3 4 5])  
=> 15
```

```
(apply str [1 2 3 4 5])  
=> "12345"
```

```
(apply inc [1])  
=> 2
```

[top](#)

## as->

```
(as-> expr name & forms)
```

Binds `name` to `expr`, evaluates the first form in the lexical context of that binding, then binds `name` to that result, repeating for each successive form, returning the result of the last form. This allows a value to thread into any argument position.

; allows to use arbitrary positioning of the argument

```
(as-> [:foo :bar] v  
      (map name v)  
      (first v)  
      (str/subs v 1))  
=> "oo"
```

; allows the use of if statements in the thread

```
(as-> {:a 1 :b 2} m  
      (update m :a #(+ % 10))  
      (if true  
        (update m :b #(+ % 10))  
        m))  
=> {:a 11 :b 12}
```

## cond

(cond & clauses)

Takes a set of test/expr pairs. It evaluates each test one at a time. If a test returns logical true, cond evaluates and returns the value of the corresponding expr and doesn't evaluate any of the other tests or exprs. (cond) returns nil.

```
(let [n 5]
  (cond
    (< n 0) "negative"
    (> n 0) "positive"
    :else "zero"))
=> "positive"
```

[top](#)

## condp

(condp pred expr & clauses)

Takes a binary predicate, an expression, and a set of clauses.

Each clause can take the form of either:

```
test-expr result-expr
test-expr :>> result-fn
```

Note :>> is an ordinary keyword.

For each clause, (pred test-expr expr) is evaluated. If it returns logical true, the clause is a match. If a binary clause matches, the result-expr is returned, if a ternary clause matches, its result-fn, which must be a unary function, is called with the result of the predicate as its argument, the result of that call being the return value of condp. A single default expression can follow the clauses, and its value will be returned if no clause matches. If no default expression is provided and no clause matches, a VncException is thrown.

```
(condp some [1 2 3 4]
  #{0 6 7} :>> inc
  #{4 5 9} :>> dec
  #{1 2 3} :>> #(* % 10))
=> 3

  neg? -1
  (constantly true) 0)
=> 1
```

## conj

```
(conj)
(conj x)
(conj coll x)
(conj coll x & xs)
```

Returns a new collection with the `x`, `xs` 'added'. `(conj nil item)` returns `(item)`. For list, vectors and ordered maps the values are added at the end. For all other sets and maps the position is undefined.

```
(conj [1 2 3] 4)

## crypt/decrypt

```
(crypt/decrypt algorithm passphrase & options)
```

Returns a new function to decrypt a string or a bytebuf given the algorithm and passphrase. If a string is passed it is base64 decoded, decrypted, and returned as string. If a bytebuf is passed the decrypted bytebuf is returned.  
Supported algorithms: "DES", "3DES", "AES256"

Options:

:url-safe enabled

The boolean option directs the base64 decoder to decode standard or URL safe base64 encoded strings.  
If enabled (true) the base64 decoder will convert '-' and '\_' characters back to '+' and '/' before decoding.  
Defaults to false.

```
(do
  (load-module :crypt)
  (def decrypt (crypt/encrypt "3DES" "secret" :url-safe true))

## crypt/encrypt

```
(crypt/encrypt algorithm passphrase & options)
```

Returns a new function to encrypt a string or a bytebuf given the algorithm and passphrase. If a string is passed it is encrypted and returned as a base64 encoded string. If a bytebuf is passed the encrypted bytebuf is returned.

Supported algorithms: "DES", "3DES", "AES256"

Options:

:url-safe enabled

The boolean option directs the base64 encoder to emit standard or URL safe base64 encoded strings.

If enabled (true) the base64 encoder will emit '-' and '\_' instead of the usual '+' and '/' characters.

Defaults to false.

Note: no padding is added when encoding using the URL-safe alphabet.

```
(do
  (load-module :crypt)
  (def encrypt (crypt/encrypt "3DES" "secret" :url-safe true))
  (encrypt "hello") ; => "ndmW1NLsDHA"

## future

```
(future fn)

Takes a function and yields a future object that will invoke the function in another thread, and will cache the result and return it on all subsequent calls to `deref`. If the computation has not yet finished, calls to `deref` will block, unless the variant of `deref` with timeout is used. Thread local vars will be inherited by the future child thread. Changes of the child's thread local vars will not be seen on the parent.

## halt-when

```
(halt-when pred)
(halt-when pred retf)
```

Returns a transducer that ends transduction when `pred` returns true for an input. When `retf` is supplied it must be a fn of 2 arguments - it will be passed the (completed) result so far and the input that triggered the predicate, and its return value (if it does not throw an exception) will be the return value of the transducer. If `retf` is not supplied, the input that triggered the predicate will be returned. If the predicate never returns true the transduction is unaffected.

## reduce

```
(reduce f coll)
(reduce f val coll)
```

`f` should be a function of 2 arguments. If `val` is not supplied, returns the result of applying `f` to the first 2 items in `coll`, then applying `f` to that result and the 3rd item, etc. If `coll` contains no items, `f` must accept no arguments as well, and `reduce` returns the result of calling `f` with no arguments. If `coll` has only 1 item, it is returned and `f` is not called. If `val` is supplied, returns the result of applying `f` to `val` and the first item in `coll`, then applying `f` to that result and the 2nd item, etc. If `coll` contains no items, returns `val` and `f` is not called.

```
(reduce (fn [x y] (+ x y)) [1 2 3 4 5 6 7])
=> 28

(reduce (fn [x y] (+ x y)) 10 [1 2 3 4 5 6 7])

=> {:a [:a 1] :b [:b 2] :c [:c 3]}
```

## reduce-kv

```
(reduce-kv f init coll)
```

Reduces an associative collection. `f` should be a function of 3 arguments. Returns the result of applying `f` to `init`, the first key and the first value in `coll`, then applying `f` to that result and the 2nd key and value, etc. If `coll` contains no entries, returns `init` and `f` is not called. Note that `reduce-kv` is supported on vectors, where the keys will be the ordinals.

```
(reduce-kv (fn [x y z] (assoc x z y)) {} {:a 1 :b 2 :c 3})
=> {1 :a 2 :b 3 :c}
```

## reduced

## set?

```

Returns true if obj is a set

```
(set? (set 1))
=> true
```

## sh

```
(sh & args)
```

Passes the given strings to `Runtime.exec()` to launch a sub-process.

Options are

- `:in`            may be given followed by input source as `InputStream`, `Reader`, `File`, `ByteBuf`, or `String`, to be fed to the sub-process's `stdin`.
- `:in-enc`       option may be given followed by a `String`, used as a character encoding name (for example `"UTF-8"` or `"ISO-8859-1"`) to convert the input string specified by the `:in` option to the sub-process's `stdin`. Defaults to `UTF-8`. If the `:in` option provides a byte array, then the bytes are passed unencoded, and this option is ignored.
- `:out-enc`       option may be given followed by `:bytes` or a `String`. If a `String` is given, it will be used as a character encoding name (for example `"UTF-8"` or `"ISO-8859-1"`) to convert the sub-process's `stdout` to a `String` which is returned. If `:bytes` is given, the sub-process's `stdout` will be stored in a `Bytebuf` and returned. Defaults to `UTF-8`.
- `:out-fn`       a function with a single string argument that receives line by line from the process' `stdout`. If passed the `:out` value in the return map will be empty.
- `:err-fn`       a function with a single string argument that receives line by line from the process' `stderr`. If passed the `:err` value in the return map will be empty.
- `:env`           override the process `env` with a map.
- `:dir`           override the process `dir` with a `String` or `java.io.File`.
- `:throw-ex`     If true throw an exception if the exit code is not equal to zero, if false returns the exit code. Defaults to false. It's recommended to use `(with-sh-throw (sh "foo"))` instead.

You can bind `:env`, `:dir` for multiple operations using `with-sh-env` or `with-sh-dir`. `with-sh-throw` is binds `:throw-ex` as true.

`sh` returns a map of

- `:exit` => sub-process's exit code
- `:out`   => sub-process's `stdout` (as `Bytebuf` or `String`)
- `:err`   => sub-process's `stderr` (`String` via platform default encoding)

## trampoline

```
(trampoline f)
```

```
(trampoline f & args)
```

trampoline can be used to convert algorithms requiring mutual recursion without stack consumption. Calls f with supplied args, if any. If f returns a fn, calls that fn with no arguments, and continues to repeat, until the return value is not a fn, then returns that non-fn value. Note that if you want to return a fn as a final value, you must wrap it in some data structure and unpack it after trampoline returns.

## transduce

```
(transduce xform f coll)
(transduce xform f init coll)
```

Reduce with a transformation of a reduction function f (xf). If init is not supplied, (f) will be called to produce it. f should be a reducing step function that accepts both 1 and 2 arguments. Returns the result of applying (the transformed) xf to init and the first item in coll, then applying xf to that result and the 2nd item, etc. If coll contains no items, returns init and f is not called.
