add-watch

```
(add-watch ref key fn)
```

Adds a watch function to an agent/atom reference. The watch fn must be a fn of 4 args: a key, the reference, its old-state, its new-state.

```
(do

```

Creates and returns an agent with an initial value of state and zero or more options.

```
Options:
   :error-handler handler-fn
   :error-mode mode-keyword
   :validator validate-fn
```
The handler-fn is called if an action throws an exception. It's afunction taking two args the agent and the exception. The mode-keyword may be either :continue (the default) or :fail The validate-fn must be nil or a side-effect-free fn of one argument, which will be passed the intended new state on any state change. If the new state is unacceptable, the validate-fn should return false or throw an exception.

SEE ALSO

or
Ors the predicate forms

not
Returns true if x is logical false, false otherwise.

any-pred

```
(any-pred p1 & p)
```

Takes a set of predicates and returns a function f that returns the first logical true value returned by one of its composing predicates against any of its arguments, else it returns logical false. Note that f is short-circuiting in that it will stop execution on the first argument that triggers a logical true result against the original predicates.

```
((any-pred number?) 1)
=> true
```

```
((any-pred number?) 1 "a")
=> true
```

```
((any-pred number? string?) 2 "a")
=> true
```

any?

```
(any? pred coll)
```

Returns true if the predicate is true for at least one collection item, false otherwise.

```
(any? number? nil)
=> false

(any? number? [])
=> false

(any? number? [1 :a :b])
=> true

(any? number? [1 2 3])
=> true

(any? #(== % 10) [10 20 30])
=> true

(any? #(>= % 10) [1 5 10])
=> true
```

app/build

```
(app/build name main-file file-map dest-dir)
```

Creates a Venice application archive that can be distributed and executed as a single file.

```
E.g.:
(app/build "test"
           "chart.venice"
           { "chart.venice" "./foo/chart.venice"
             "utils.venice" "./foo/utils.venice" }
           ".")
```

Loading Venice files works relative to the application. You can only load files that are in the app archive. If for instances "chart.venice" in the above example requires "utils.venice" just add (load-file "utils") to "chart.venice".

```
The app can be run from the command line as:
> java -jar venice-1.7.17.jar -app test.zip

Or with additional Java libraries (all JARs in 'libs' dir):
> java -cp "libs/*" com.github.jlangch.venice.Launcher -app test.zip
```

app/manifest

```
(app/manifest app)
```

Returns the manifest of a Venice application archive.

apply

```
(apply f args* coll)
```

Applies f to all arguments composed of args and coll

```
(apply + [1 2 3])
=> 6

(apply + 1 2 [3 4 5])
=> 15

(apply str [1 2 3 4 5])
=> "12345"

(apply inc [1])
=> 2
```

as->

```
(as-> expr name & forms)
```

Binds name to expr, evaluates the first form in the lexical context of that binding, then binds name to that result, repeating for each successive form, returning the result of the last form. This allows a value to thread into any argument position.

```
; allows to use arbitrary positioning of the argument
(as-> [:foo :bar] v
      (map name v)
      (first v)
      (str/subs v 1))
=> "oo"

; allows the use of if statements in the thread
(as-> {:a 1 :b 2} m
      (update m :a #(+ % 10))
      (if true
        (update m :b #(+ % 10))
        m))
=> {:a 11 :b 12}
```

(cond) returns nil.

Takes an expression and a set of test/form pairs. Threads expr (via ->) through each form for which the
corresponding test expression is true. Note that, unlike cond branching, cond-> threading does not short
circuit after the first true test expression.

It is useful in situations where you want selectively assoc, update, or dissoc something from a map.

condp

```
(condp pred expr & clauses)
```

Takes a binary predicate, an expression, and a set of clauses.
Each clause can take the form of either:
    test-expr result-expr
    test-expr :>> result-fn
Note :>> is an ordinary keyword.
For each clause, (pred test-expr expr) is evaluated. If it returns logical true, the clause is a match. If a binary clause matches, the result-expr is returned, if a ternary clause matches, its result-fn, which must be a unary function, is called with the result of the predicate as its argument, the result of that call being the return value of condp. A single default expression can follow the clauses, and its value will be returned if no clause matches. If no default expression is provided and no clause matches, a VncException is thrown.

```

```
Options:
  :url-safe enabled
      The boolean option directs the base64 decoder to decode
      standard or  URL safe base64 encoded strings.
      If enabled (true) the base64 decoder will convert '-' and '_'
      characters back to '+' and '/' before decoding.
      Defaults to false.

crypt/encrypt

```
(crypt/encrypt algorithm passphrase & options)

returned.
Supported algorithms: "DES", "3DES", "AES256"

```
Options:
  :url-safe enabled
      The boolean option directs the base64 encoder to emit
      standard or URL safe base64 enoded strings.
      If enabled (true) the base64 encoder will emit '-' and '_'
      instead of the usual '+' and '/' characters.
      Defaults to false.
      Note: no padding is added when encoding using the
            URL-safe alphabet.

The variant taking a timeout can be used for futures and will return timeout-val if the timeout (in milliseconds) is reached before a value is available. If a future is deref'd and the waiting thread is interrupted the futures are cancelled.

future

```
(future fn)
```

Takes a function without arguments and yields a future object that will invoke the function in another thread, and will cache the result and return it on all subsequent calls to deref. If the computation has not yet finished, calls to deref will block, unless the variant of deref with timeout is used.
Thread local vars will be inherited by the future child thread. Changes of the child's thread local vars will not be seen on the parent.

```
(do
   (def wait (fn [] (do (sleep 300) 100)))
   (let [f (future wait)]

predicate, and its return value (if it does not throw an exception) will be the return value of the If retf is
not supplied, the input that triggered the predicate will be returned. If the predicate never returns true the
transduction is unaffected.

Sequentially read and evaluate the set of forms contained in the file.
If the file can not be found on the global load paths and and the sandbox permits the file is either loaded from the current working directory if it has a relative path or it is loaded from its absolute path.
With 'force' set to false (the default) the file is only loaded once and then served from a cache. With 'force' set to true it is always loaded physically.
The function is restricted to load files with the extension '.venice'. If the file extension is missing '.venice' will be implicitely added.
Returns 'true' if the file has been successfully loaded and 'false' if the file has been already loaded. Throws an exception on loading error.

Returns a collection of lists of n items each, at offsets step apart. If step is not supplied, defaults to n, i. e. the partitions do not overlap. If a padcoll collection is supplied, use its elements as necessary to complete last partition upto n items. In case there are not enough padding elements, return a partition with less than n items. padcoll may be a lazy sequence

SEE ALSO

loop
Evaluates the exprs and binds the bindings. Creates a recursion point with the bindings.

reduce

```
(reduce f coll)
(reduce f val coll)
```

f should be a function of 2 arguments. If val is not supplied, returns the result of applying f to the first 2 items in coll, then applying f to that result and the 3rd item, etc. If coll contains no items, f must accept no arguments as well, and reduce returns the result of calling f with no arguments. If coll has only 1 item, it is returned and f is not called. If val is supplied, returns the result of applying f to val and the first item in coll, then applying f to that result and the 2nd item, etc. If coll contains no items, returns val and f is not called.

```
(reduce (fn [x y] (+ x y)) [1 2 3 4 5 6 7])
=> 28

(reduce (fn [x y] (+ x y)) 10 [1 2 3 4 5 6 7])
=> 38

=> {:a [:a 1] :b [:b 2] :c [:c 3]}
```

reduce-kv

```
(reduce-kv f init coll)
```

Reduces an associative collection. f should be a function of 3 arguments. Returns the result of applying f to init, the first key and the first value in coll, then applying f to that result and the 2nd key and value, etc. If coll contains no entries, returns init and f is not called. Note that reduce-kv is supported on vectors, where the keys will be the ordinals.

```
(reduce-kv (fn [m k v] (assoc m v k))
           {}
           {:a 1 :b 2 :c 3})
=> {1 :a 2 :b 3 :c}

sh

```
(sh & args)
```

```
Passes the given strings to Runtime.exec() to launch a sub-process.

Options are
  :in        may be given followed by input source as InputStream,
             Reader, File, ByteBuf, or String, to be fed to the
             sub-process's stdin.
  :in-enc    option may be given followed by a String, used as a
             character encoding name (for example "UTF-8" or
             "ISO-8859-1") to convert the input string specified
             by the :in option to the sub-process's stdin. Defaults
             to UTF-8. If the :in option provides a byte array,
             then the bytes are passed unencoded, and this option
             is ignored.
  :out-enc   option may be given followed by :bytes or a String. If
             a String is given, it will be used as a character
             encoding name (for example "UTF-8" or "ISO-8859-1")
             to convert the sub-process's stdout to a String which is
             returned. If :bytes is given, the sub-process's stdout
             will be stored in a Bytebuf and returned. Defaults to
```

```
            UTF-8.
  :out-fn    a function with a single string argument that receives
             line by line from the process' stdout. If passed the
             :out value in the return map will be empty.
  :err-fn    a function with a single string argument that receives
             line by line from the process' stderr. If passed the
             :err value in the return map will be empty.
  :env       override the process env with a map.
  :dir       override the process dir with a String or java.io.File.
  :throw-ex  If true throw an exception if the exit code is not equal
             to zero, if false returns the exit code. Defaults to
             false. It's recommended to use (with-sh-throw (sh "foo"))
             instead.

You can bind :env, :dir for multiple operations using with-sh-env or
with-sh-dir. with-sh-throw is binds :throw-ex as true.

sh returns a map of
  :exit => sub-process's exit code
  :out  => sub-process's stdout (as Bytebuf or String)
  :err  => sub-process's stderr (String via platform default encoding)

trampoline

```
(trampoline f)
(trampoline f & args)
```

trampoline can be used to convert algorithms requiring mutual recursion without stack consumption. Calls f with
supplied args, if any. If f returns a fn, calls that fn with no arguments, and continues to repeat, until the
return value is not a fn, then returns that non-fn value.
Note that if you want to return a fn as a final value, you must wrap it in some data structure and unpack it
after trampoline returns.

transduce

```
(transduce xform f coll)
(transduce xform f init coll)
```

Reduce with a transformation of a reduction function f (xf). If init is not supplied, (f) will be called to produce it. f should be a reducing step function that accepts both 1 and 2 arguments. Returns the result of applying (the transformed) xf to init and the first item in coll, then applying xf to that result and the 2nd item, etc. If coll contains no items, returns init and f is not called.

```

  (def xform (map #(+ % 1)))
